# 1. Mathematical modeling

- Network growth under preferential attachment. (UMass, Columbia, Cornell)
- Generating mechanisms for multivariate heavy tails. (UMass, Cornell)
- Models for mobility, eg wireless networks. (OSU)
- Competition models under cumulative advantage; related to preferential attachment and generates games with heavy tailed durations. Cumulative advantage like preferential attachment may be linear or non-linear function of *fitness*. (UMass)
- Models to aid visual search. (UMass, Illinois)
  - Searching for suspects from a huge number of images.
  - Matching images when resolution is low in one image.
- Semi-parametric and asymptotic techniques for risk estimation. (Cornell)
- Methods for dimension reduction for multivariate heavy tailed data (ICA, PCA, ...). (Columbia, American)

## 2. Data exploration, inference and network analysis.

- Sampling issues: how to sample large networks under budget constraints to achieve estimation of summary quantities? (UMass, Columbia, Cornell, Minn)
- Node classification: Questions are suggested by difficulties in sampling sensibly. Nodes may have multivariate characters: in- and out-degree, strength of friendliness, strength of foe-y-ness, etc. (UMass, Cornell)

- Algorithms for matching large networks. (Illinois, UMass, Mn)
  - When are two networks similar?
  - Heavy tailed node degrees help the algorithm; match large degree nodes first.

- Calibration, simulation of a preferential attachment model. (UMass, Columbia, Cornell)

- Efficiency loss from estimation using one snapshot vs network evolution;
- stationary vs change-point analysis;
- asymptotic parametric methods (more robust) vs MLE parametric methods (more fragile but more accurate).

- Methods for exploring reciprocity (% of node pairs with bi-directional edges) in large directed graphs. How do reciprocal node pairs affect evolution and social structure? They form a core subgraph to which other nodes are attached. (Minn, UMass, Cornell)

- Mining geoMobility data (wireless users, bike-share, ambulance movement). Framework for study: EPIC. (Minn)
- Inference for heavy tail data (Columbia, Cornell)
  - Large values may be missing, lost, not-recorded.
  - Large values may be censored by rules. Must still do inference.
  - Limitations of minimum distance (Clausett) methods for threshold selection to decide what data has information about the tail.

### 3. Scheduling and control in multivariate heavy tailed environments.

- Emulating round robin scheduling in wireless networks. (Illinois)
  - Used for wireline where it is not sensitive to distributional properties of the file size distribution.
  - Military scenarios.
  - Goals to achieve: fairness, good throughput, small delay.
- Routing in cloud computing. (OSU, Illinois)
  - Massive data analysis is often needed to prepare for battle, to track adversaries, and for other military applications.
  - Routing algorithm that is insensitive to service time distribution.
  - Goals: Fast data retrieval, fast computation.
- Influence propagation in evolving networks. (Minn, OSU)

- Mobile data offloading: (OSU)
  - Cellular networks often highly constrained.
  - Suggests offloading some traffic to wifi or wired LANS.
- Context aware application scheduling for increasing battery life-time and improving application response times in smartphones. (OSU)
  - Probability of launching an app follows Zipf's law.
  - The inter-run time and run time of an app follow multivariate heavy tail law.
  - Which apps held in memory and which should be closed?

## 4. Software.

Nolan (American) packages in R environment posted on CRAN (Comprehensive R Archive Network) at <https://cran.r-project.org>.

1. **mvmesh**. - a package to define and work with MultiVariate Meshes in  $n$  dimensions.

- Define common shapes - hollow and solid spheres, simplices, rectangles, and tubes.
- Plot these objects in 2 and 3 dimensions.
- Define and manipulate shapes in higher dimensions.
- Multivariate histogram functions
  - Count the number of data points in partitions of any of the above shapes,
  - Directional histograms that tally how many points are in a list of cones.

2. **SphericalCubature.** - a package to evaluate integrals over spheres in  $n$  dimensions. Gives exact formulas for polynomial integrands and adaptive methods for general functions.

3. **SimplicialCubature.** - a package to evaluate integrals over  $n$  dimensional simplices. Gives exact formulas for polynomial integrands and adaptive methods for general functions.

4. **gensphere.** - a package to define probability distributions that have level sets that are all scaled versions of a fixed contour.

- Specify a large family of contours.
- Define a probability distribution in terms of that contour and a radial decay function.
- Arose out of previous Nat- ick visit over attempts to model fragment dispersion from explosions.

4. **ecdfHT**. - a package for computing and plotting a transformed empirical cumulative distribution function (ecdf) for heavy tailed data.

- Uses log-log transform with extremes pulled in to get visual diagnostic for heavy tails.
- If plot suggests power law behavior, there are functions to estimate the exponent of the decay and the scale constant.
- Multivariate generalizations are developed.

5. **mvevd**. (Under development:) Implements several dense classes of multivariate extreme value distributions.

- discrete angular measure,
- generalized logistic,
- piecewise constant and linear angular measures.
- Uses tools from the `mvmesh` and `SimplicialCubature` packages to work in dimension  $n > 2$ .
